Methods

Data

We downloaded data from Coronavirus COVID-19 (2019-nCoV) Data Repository for South Africa maintained by Data Science for Social Impact research group at the University of Pretoria [ref]. The data repository captures the daily number of new cases, number of tests, number of deaths and recoveries. Our primary outcome of interest was the daily number of newly diagnosed COVID-19 cases and the unit of time used in modelling was a day. We used the daily case reports from March 12, 2020, until February 27, 2021, in our analysis.

## Statistical analysis

We considered two widely used temporal models to model the daily number of newly diagnosed COVID-19 cases. We let Y(t) denote the daily number of newly diagnosed COVID-19 cases at time t and  $\mu(t)$  represent the expected number of cases at time t. We considered a Negative binomial distribution for Y(t) to account for possible overdispersion. That is,  $Y(t) \sim NB(\mu(t), \delta)$ , where  $\delta$  is the overdispersion parameter. We considered two temporal models to capture the trend over time: a random walk of order two (RW(2)) and an autoregressive model of order one (AR(1)) [1]. We also considered a RW(1) model, but the model overfits the data (see Sece 2 in the supplementary appendix). Similarly, we considered an AR model order p=2 but the result is similar to AR1 model and we prefer the simpler AR1 model.

The AR(1) model [1] is given by,

February 28, 2021 1/6

$$Y(t) \sim NB(\mu(t), \delta) \quad t = 1, \dots, n,$$

$$log(\mu(t)) = \alpha + u_t,$$

$$u_1 \sim N(0, \tau_u (1 - \rho^2)^{-1}),$$

$$u_t = \rho u_{t-1} + \epsilon_t, \quad t = 2, \dots, n,$$

$$\epsilon_t \sim N(0, \tau_\epsilon),$$

where,  $\alpha$  is an intercept,  $\rho$  a temporal correlation term (with  $|\rho| < 1$ ) and  $\epsilon_t$  is a Gaussian error term with zero mean and precision  $\tau_{\epsilon}$ .

Similarly, the RW(2) model [1] is given by,

$$Y(t) \sim NB(\mu(t), \delta) \ t = 1, \dots, n,$$
  
 $log(\mu(t)) = \alpha + u_t,$   
 $u_t - 2u_{t+1} + u_{t+2} \sim N(0, \tau_u), \ t = 2, \dots, n,$ 

where  $\alpha$  is the intercept term as before and  $\tau_u$  is the precision parameter.

The two models were fitted within the Bayesian framework using inla [2]. To complete the specification of both models, we assume the following priors. For the AR(1) model, we denote  $\theta_1 = log(\tau_u(1-\rho^2))$  where  $\Gamma(10,100)$  prior is specified for  $\theta_1$ , and we denote  $\theta_2 = log\frac{1+\rho}{1-\rho}$  and assume a N(0,0.15) prior for  $\theta$ . Similarly, we represent the precison parameter of RW(1),  $\tau_u$ , as  $\theta = log(\tau_u)$  and assume a  $\Gamma(10,100)$  prior for  $\theta$ . To assess the models' accuracy in predicting cases, we present the forecast period's actual observed values and the predicted values. Additionally, the model fits were evaluated by using DIC (Deviance information criteria). The computer code that we used for our analyses is available at https://github.com/belayb/COVIDincidenceSA/tree/master/COVIDincidenceSA.

Results

Figure 1 presents the daily number of reported COVID-19 cases from 12 March 2020 to 27 February 2021. Similar to elsewhere in the world, South Africa pass through a two-wave pandemic. The pandemic's first peak was on 07 July 2020, where up to 13944 new COVID-19 cases reported, followed by a second peak in January 2021, where more than 21,000 daily cases reported. Figure 2 presents the cumulative number of new reported COVID-19 cases and tests performed. To date, 8,838,937 tests have been conducted, and a total of 1,500,677 cases reported.

## Short-term prediction of the total number of reported COVID-19 cases

We fit the two models described in the previous section to the daily reported new COVID-19 cases. The parameter estimates for the two models are presented in Supplementary Table 1. As depicted in Figure 3, two models fitted to the data appear to fit the observed data (within the estimation period) well with a narrow confidence interval obtained for the RW(2) model. The two models provides similar predictions over the 7-day ahead period.

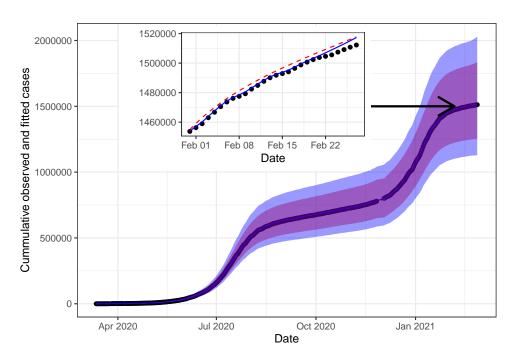

Fig 5. Predicted cummulative COVID-19 cases in South Africa under the RW(1) and AR(1) model. Estimation period 12/03/2020-20/02/2021. The black dots are the observed cummulative cases. The red dashed lines are for RW(2) and the blue line for AR(1). The shaded bands are the prediction intervals.
